# Online Supplement

## Supplemental Materials for: Compensatory Faking and the Relationship Between Cognitive Ability and Personality in Personnel Selection

This supplement contains the benchmark comparison against published database estimates (Table S1), the full five-context meta-analytic estimates (Table S2), robustness and bias analyses (Tables S3–S4), era and within-applicant moderator analyses (Table S5), the analytic composite grid (Table S6, Figure S1), Monte Carlo sensitivity runs with fitted inflation parameters (Table S7), a sensitivity analysis appending the operational mega-samples reported by Schilling et al. (2021) (Table S8), prevalence sensitivity runs for both Monte Carlo models (Table S9), the six-target refit of the Study 2 inflation functional forms (Table S10), selection outcomes for every trait–faking anchor set under a uniform reporting rule (Table S11), sample-level forest plots for the four Big Five traits not shown in the main text (Figures S2–S5), and a forest plot of Conscientiousness applicant samples split by region (Figure S6). All values are produced by the scripted pipeline described in the manuscript's Method section.

**Table S1**

*Comparison of Total-Database Estimates From the Present Pipeline With Published Stanek and Ones (2023a) Values*

| Trait | Present pipeline, total database ρ | Stanek & Ones (2023a) published value | Correspondence |
|---|---|---|---|
| Neuroticism | −.08 | mean $\hat{\rho}$ = −.07 across abilities, mean 95% CI [−.11, −.02] | within published CI |
| Extraversion | −.02 | "negligibly related to cognitive abilities" | consistent |
| Openness | .26 | $\hat{\rho}$ = .26 with GMA, 95% CI [.25, .27] | exact match |
| Agreeableness | −.01 | "weakest relations with cognitive abilities" | consistent |
| Conscientiousness | .01 | global relations "weaker and less consistent than its aspects and facets" | consistent |

*Note.* Present-pipeline values are *N*-weighted mean observed correlations for all contexts pooled, corrected with constant artifact values (personality reliability = .80, GMA reliability = .85). Published values are from the Stanek and Ones (2023a) text and Table 1, which use artifact distributions; differences of .01–.02 are expected from the differing correction procedures. Published quotations characterize global-factor relations where exact GMA point values are reported only graphically. The published syntheses pool across assessment contexts; none of the stakes, regional, or era moderator analyses in the present study appear in Stanek and Ones (2023a, 2023b). GMA = general mental ability.

**Table S2**

*Bare-Bones Meta-Analytic Big Five–GMA Correlations by Assessment Context (All Five Contexts)*

| Trait / Context | *k* | *N* | $\bar{r}$ | 95% CI | $SD_{res}$ | 80% CV | ρ |
|---|---|---|---|---|---|---|---|
| **Neuroticism** | | | | | | | |
| High stakes (applicants) | 21 | 22,775 | −.11 | [−.14, −.08] | .07 | [−.20, −.02] | −.14 |
| Low stakes (incumbents) | 83 | 20,634 | −.10 | [−.12, −.07] | .10 | [−.23, .03] | −.12 |
| Low stakes (students) | 295 | 84,840 | −.06 | [−.07, −.04] | .07 | [−.15, .04] | −.07 |
| Low stakes (community) | 93 | 73,310 | −.07 | [−.09, −.06] | .05 | [−.14, −.01] | −.09 |
| Military (mixed stakes) | 36 | 31,580 | −.10 | [−.12, −.08] | .06 | [−.18, −.03] | −.12 |
| **Extraversion** | | | | | | | |
| High stakes (applicants) | 15 | 13,137 | .02 | [−.02, .05] | .06 | [−.07, .10] | .02 |
| Low stakes (incumbents) | 66 | 16,822 | .03 | [.01, .05] | .08 | [−.07, .13] | .04 |
| Low stakes (students) | 263 | 95,564 | −.02 | [−.03, −.01] | .08 | [−.13, .08] | −.03 |
| Low stakes (community) | 92 | 76,025 | −.02 | [−.03, .00] | .07 | [−.10, .07] | −.02 |
| Military (mixed stakes) | 21 | 16,140 | −.01 | [−.05, .02] | .06 | [−.10, .07] | −.02 |
| **Openness** | | | | | | | |
| High stakes (applicants) | 13 | 13,756 | .14 | [.12, .17] | .04 | [.09, .20] | .17 |
| Low stakes (incumbents) | 49 | 10,634 | .15 | [.12, .18] | .09 | [.04, .26] | .18 |
| Low stakes (students) | 198 | 74,456 | .17 | [.15, .19] | .15 | [−.02, .36] | .21 |
| Low stakes (community) | 60 | 52,544 | .23 | [.21, .25] | .08 | [.14, .33] | .28 |
| Military (mixed stakes) | 19 | 9,861 | .13 | [.10, .17] | .07 | [.05, .22] | .16 |
| **Agreeableness** | | | | | | | |
| High stakes (applicants) | 11 | 18,848 | .02 | [−.02, .05] | .05 | [−.05, .09] | .02 |
| Low stakes (incumbents) | 64 | 17,238 | .00 | [−.03, .02] | .08 | [−.11, .10] | .00 |
| Low stakes (students) | 200 | 75,721 | −.01 | [−.03, .00] | .08 | [−.11, .09] | −.02 |
| Low stakes (community) | 45 | 49,694 | −.04 | [−.06, −.02] | .06 | [−.12, .04] | −.05 |
| Military (mixed stakes) | 23 | 21,006 | .02 | [−.01, .06] | .07 | [−.07, .11] | .03 |
| **Conscientiousness** | | | | | | | |
| High stakes (applicants) | 20 | 20,757 | −.07 | [−.14, .00] | .16 | [−.28, .13] | −.09 |
| Low stakes (incumbents) | 71 | 18,242 | .03 | [.01, .06] | .10 | [−.09, .16] | .04 |
| Low stakes (students) | 173 | 58,015 | −.02 | [−.04, −.01] | .06 | [−.10, .06] | −.03 |
| Low stakes (community) | 57 | 54,120 | .00 | [−.02, .02] | .06 | [−.08, .08] | .00 |
| Military (mixed stakes) | 22 | 21,372 | .01 | [−.02, .04] | .06 | [−.07, .09] | .01 |

*Note.* *k* = number of independent samples; *N* = total sample size; $\bar{r}$ = *N*-weighted mean observed correlation; CI = confidence interval; $SD_{res}$ = residual standard deviation after removing sampling-error variance; CV = credibility interval; ρ = mean correlation corrected for measurement error in both variables (personality reliability = .80, GMA reliability = .85). GMA = general mental ability. Applicant versus all-pooled-low-stakes contrasts: Neuroticism Δ = −.04, 95% CI [−.08, −.01], *p* = .011; Extraversion Δ = +.03 [−.01, .07], *p* = .101; Openness Δ = −.05

[−.08, −.02], $p$ = .003; Agreeableness Δ = +.04 [.01, .08], $p$ = .026; Conscientiousness Δ = −.07 [−.14, .00], $p$ = .063.

**Table S3**

*Sensitivity Analyses for the Focal Conscientiousness–GMA Contrast*

| Analysis | Applicant estimate | Incumbent estimate | Notes |
|---|---|---|---|
| Bare-bones (primary) | −.07 [−.14, .00] | .03 [.01, .06] | $\Delta = -.11$ [−.18, −.03], $z = -2.78$, $p = .005$ |
| DerSimonian–Laird random effects | −.10 [−.19, −.02] | .03 [−.01, .06] | Fisher-*z* scale, back-transformed |
| WLS meta-regression (year, % male, age) | $b_{\text{high-stakes}} = -.16$ | — | $p = .07$, HC1 robust standard errors |
| Leave-one-out ($k = 20$) | −.14 to −.04 | — | Mean negative in all 20 re-estimates; 95% CI excludes zero in 14 of 20. The largest shift comes from omitting the largest sample (Hough et al., 1993; $r = +.04$, $N =$ 7,868), which moves the estimate to −.14 [−.22, −.07] |
| Egger regression | intercept $p = .41$ | — | No funnel asymmetry |
| PET / PEESE | −.04 / −.08 | — | Adjusted estimates remain negative |
| Reliability grid | range < .02 | — | ρ across personality $r_{xx} \in \{.75, .80, .85\}$ × GMA $r_{xx} \in$ {.80, .85, .90} |

*Note.* GMA = general mental ability; WLS = weighted least squares; PET = precision-effect test; PEESE = precision-effect estimate with standard error.

**Table S4**

*Publication-Bias Diagnostics for Applicant Pools (All Big Five Traits)*

| Trait | Egger *p* | PET estimate | PEESE estimate |
|---|---|---|---|
| Neuroticism | .08 | −.15 | −.12 |
| Conscientiousness | .41 | −.04 | −.08 |

*Note.* Neuroticism's marginal asymmetry is in the direction of making the applicant estimate conservative. Remaining traits showed no asymmetry (all $p > .10$); full output is available from the author.

**Table S5**

*Era and Within-Applicant Moderator Analyses*

| Analysis | Estimate | *p* |
|---|---|---|
| Applicant C–GMA: published vs. unpublished | −.09 vs. −.07 | .76 |
| Applicant C–GMA: through 2005 vs. after 2005 | −.05 vs. −.11 | .43 |
| Low-stakes O–GMA: pre-1990 vs. 2005–2013 | .27 vs. .17 | — |
| Low-stakes C–GMA and N–GMA era trends | stable | — |

*Note.* C = Conscientiousness; O = Openness; N = Neuroticism; GMA = general mental ability.

The applicant Conscientiousness estimate is more negative in recent studies, so the stakes finding is not an artifact of older data.

**Table S6**

*Composite Validity and Subgroup d for a GMA + Conscientiousness Composite Under Total-Database Versus Pooled Applicant Intercorrelation Inputs (Plug-In Model)*

| Weight on GMA | Validity, total-database input | Validity, applicant input | *d*, total-database input | *d*, applicant input |
|---|---|---|---|---|
| .00 | .190 | .190 | −0.070 | −0.070 |
| .25 | .277 | .286 | 0.183 | 0.189 |
| .50 | .352 | .371 | 0.507 | 0.534 |
| .75 | .353 | .364 | 0.725 | 0.748 |
| 1.00 | .310 | .310 | 0.790 | 0.790 |
| Optimal (regression) *R* | .362 | .379 | — | — |

*Note.* Both inputs are reliability-corrected estimates from main-text Table 3, Panel B: the total-database value ($\rho_{12}$ = +.01, all contexts pooled) and the pooled applicant value ($\rho_{12}$ = −.09). Operational validities .31 (GMA) and .19 (Conscientiousness) from Sackett et al. (2022); Black–White *d* values 0.79 (GMA; Roth et al., 2011) and −0.07 (Conscientiousness; Dahlke & Sackett, 2017), positive = higher White mean. See Figure S1. GMA = general mental ability.

**Table S7**

*Monte Carlo Sensitivity to Faking Noise and Fitted Inflation Parameters*

| Context | σ | SR | % hires changed | Loss (%) | AI ratio, honest → faked | $\mu_f$ | *b* |
|---|---|---|---|---|---|---|---|
| US | 0.25 | .10 | 33.0 | 5.9 | 0.37 → 0.37 | 1.229 | 0.012 |
| US | 0.50 | .10 | 35.8 | 10.3 | 0.40 → 0.39 | 1.252 | 0.011 |
| US | 1.00 | .10 | 42.8 | 16.3 | 0.37 → 0.39 | 1.338 | 0.009 |
| Pooled | 0.25 | .10 | 28.7 | 8.3 | 0.39 → 0.42 | 1.238 | 0.301 |
| Pooled | 0.50 | .10 | 32.3 | 8.9 | 0.39 → 0.44 | 1.261 | 0.307 |
| Pooled | 1.00 | .10 | 41.4 | 17.8 | 0.36 → 0.43 | 1.348 | 0.333 |
| Non-US | 0.25 | .10 | 26.0 | 12.9 | 0.41 → 0.56 | 1.347 | 1.064 |
| Non-US | 0.50 | .10 | 30.8 | 15.0 | 0.37 → 0.52 | 1.374 | 1.093 |
| Non-US | 1.00 | .10 | 40.7 | 23.7 | 0.38 → 0.56 | 1.477 | 1.199 |

*Note.* σ = idiosyncratic faking-noise standard deviation; SR = selection ratio; AI = adverse impact; $\mu_f$ = fitted mean inflation among fakers (in honest-score *SD* units); *b* = fitted compensatory slope on *g*. Directions of all effects are invariant to σ in every condition.

**Table S8**

*Sensitivity of Applicant Meta-Analytic Estimates to Six Operational Mega-Samples Reported by Schilling et al. (2021)*

| Estimate | *k* | *N* | $\bar{r}$ [95% CI] |
|---|---|---|---|
| **Conscientiousness** | | | |
| Present study, pooled applicants | 20 | 20,757 | −.07 [−.14, .00] |
| Plus mega-samples | 26 | 253,503 | +.06 [+.03, +.09] |
| Plus mega-samples, largest included | 27 | 2,259,742 | +.05 [+.04, +.06] |
| Present study, US applicants | 10 | 14,707 | +.01 [−.05, +.06] |
| US plus mega-samples | 15 | 228,088 | +.07 [+.04, +.10] |
| Present study, non-US applicants | 10 | 6,050 | −.27 [−.34, −.20] |
| Non-US plus mega-samples | 11 | 25,415 | +.02 [−.09, +.12] |
| **Neuroticism** | | | |
| Present study | 21 | 22,775 | −.11 [−.14, −.08] |
| Plus mega-samples | 24 | 140,710 | −.06 [−.09, −.02] |
| Plus mega-samples, largest included | 25 | 2,146,949 | −.07 [−.08, −.06] |
| **Openness** | | | |
| Present study | 13 | 13,756 | +.14 [+.12, +.17] |
| Plus mega-samples | 17 | 157,888 | +.19 [+.17, +.21] |
| Plus mega-samples, largest included | 18 | 2,164,127 | +.25 [+.24, +.26] |
| **Extraversion** | | | |
| Present study | 15 | 13,137 | +.02 [−.02, +.05] |
| Plus mega-samples | 20 | 221,861 | +.08 [+.07, +.09] |
| Plus mega-samples, largest included | 21 | 2,228,100 | +.04 [+.04, +.05] |
| **Agreeableness** | | | |
| Present study | 11 | 18,848 | +.02 [−.02, +.05] |
| Plus mega-samples | 16 | 185,943 | +.06 [+.04, +.09] |
| Plus mega-samples, largest included | 17 | 2,192,182 | +.06 [+.05, +.07] |

*Note.* Bare-bones sample-size-weighted estimates as in main-text Table 1. Mega-sample correlations were transcribed from Table S7 of Schilling et al.'s (2021) Supporting Information, which reports six operational applicant datasets excluded from their meta-analysis because the sample sizes would dominate the averages (identified there by first author and year: Levashina, 2014; MacKenzie, 2010; Delgado, 2011; Huang, 2015; Arthur, 2014, two samples; De Fruyt, 2006). Five of the six samples do not appear in the Stanek–Ones database; the De Fruyt (2006) sample does appear there (as a French applicant sample, $N = 20{,}183$, vs. $N = 19{,}365$ in Schilling et al.'s transcription) but with its cognitive measure classified as fluid/inductive reasoning rather than *g*, placing it outside the manuscript's inclusion criteria. "Plus mega-samples" excludes the single $N = 2{,}006{,}239$ Arthur sample, following Schilling et al.'s rationale; "largest included" adds

it. Emotional Stability correlations were reversed to the Neuroticism orientation. All mega-samples are US operational testing programs except De Fruyt (2006), a European applicant sample, which alone accounts for the non-US row's change. Produced by `15_schilling_s7_sensitivity.py`. GMA = general mental ability.

**Table S9**

*Sensitivity of Selection Outcomes to Faking Prevalence in Both Monte Carlo Models*

| Model | Context | SR | % changed, 20% | % changed, 30% | % changed, 40% | % changed, 50% | Loss %, 20% | Loss %, 30% | Loss %, 40% | Loss %, 50% |
|---|---|---|---|---|---|---|---|---|---|---|
| Study 1 | US | .10 | 55.7 | 43.3 | 35.8 | 30.5 | 27.3 | 14.6 | 10.3 | 8.1 |
| Study 1 | US | .30 | 29.8 | 25.9 | 22.5 | 19.7 | 18.9 | 11.6 | 8.4 | 6.8 |
| Study 1 | Pooled | .10 | 52.1 | 38.6 | 32.3 | 28.7 | 23.3 | 12.7 | 8.9 | 8.7 |
| Study 1 | Pooled | .30 | 33.8 | 26.9 | 22.5 | 19.5 | 26.1 | 15.2 | 10.8 | 9.0 |
| Study 1 | Non-US | .10 | 66.4 | 39.7 | 30.8 | 27.9 | 78.6 | 27.0 | 15.0 | 12.5 |
| Study 1 | Non-US | .30 | 43.9 | 33.0 | 26.0 | 22.4 | 53.2 | 33.2 | 18.7 | 14.5 |
| Study 2 | US | .10 | 38.7 | 37.4 | 34.9 | 31.6 | 16.6 | 13.3 | 10.4 | 8.2 |
| Study 2 | US | .30 | 19.8 | 21.5 | 21.1 | 20.0 | 9.9 | 9.6 | 8.9 | 7.4 |
| Study 2 | Pooled | .10 | 34.4 | 31.8 | 28.8 | 27.1 | 15.2 | 10.3 | 7.9 | 6.3 |
| Study 2 | Pooled | .30 | 22.1 | 22.7 | 21.5 | 20.3 | 13.4 | 11.2 | 9.2 | 7.3 |
| Study 2 | Non-US | .10 | 26.5 | 21.9 | 20.0 | 21.5 | 25.0 | 13.4 | 9.8 | 10.1 |
| Study 2 | Non-US | .30 | 29.4 | 28.1 | 25.4 | 23.5 | 36.7 | 26.8 | 17.9 | 14.2 |

*Note.* Column headers give the assumed faking prevalence. The 30%–50% range comes from within-person applicant studies (Donovan et al., 2014; Griffith et al., 2007); 20% is the lower bound of the Griffith and Converse (2011) evidence synthesis, which concludes 30% ±10%; 40% is the primary specification reported in the main text. Prevalence denotes the proportion of applicants who fake at all (the any-scale rate the within-person studies report), matching each model's binary faker indicator. All model parameters were refit at each prevalence so that every pool reproduces the same empirical targets. Study 1 = random-faker Monte Carlo model (main-text Table 4); Study 2 = trait-driven model, field-conservative anchors with targeted linear inflation (main-text Table 6). % changed = percentage of top-down hires that differ from the honest counterfactual; Loss % = percentage reduction in mean true performance of hires; SR = selection ratio. Because the fitted inflation parameters must reproduce the same pool-level evidence at any prevalence, lower prevalence concentrates larger inflation in fewer applicants and produces worse outcomes; the one exception (Study 2, non-US, SR = .10, 40% vs. 50%) is a 0.4-point difference within Monte Carlo error. The Study 1 cells at 20% prevalence should be

read as an upper bound on harm rather than as a realistic scenario: reproducing the Birkeland et al. (2006) mean shift with so few fakers requires per-faker mean inflation of 3.0–4.8 *SD*, which bounded response scales would not permit; the trait-driven Study 2 model, which fits inflation against six targets including the observed variance ratio, degrades far more gradually.

**Table S10**

*Six-Target Refit of the Study 2 Inflation Functional Forms (Field-Conservative Anchors)*

| Context | Form | Weighted distance | Distance above A component | Loss %, SR = .10 | Loss %, SR = .30 | H gap, HEXACO | H gap, overt tests |
|---|---|---|---|---|---|---|---|
| US | Linear | 6.20 | 2.67 | 10.4 | 8.9 | −0.19 | −0.32 |
| US | Censored | 4.36 | 0.83 | 18.3 | 15.6 | −0.41 | −0.67 |
| US | Freed skill | 4.30 | 0.77 | 18.2 | 17.5 | −0.38 | −0.63 |
| Pooled | Linear | 4.95 | 1.42 | 7.9 | 9.2 | −0.22 | −0.33 |
| Pooled | Censored | 4.25 | 0.72 | 17.1 | 17.2 | −0.49 | −0.75 |
| Pooled | Freed skill | 4.12 | 0.59 | 13.4 | 16.6 | −0.39 | −0.63 |
| Non-US | Linear | 4.90 | 1.38 | 9.8 | 17.9 | −0.45 | −0.70 |
| Non-US | Censored | 7.11 | 3.58 | 21.2 | 30.5 | −0.84 | −1.26 |
| Non-US | Freed skill | 4.89 | 1.37 | 11.1 | 19.8 | −0.47 | −0.74 |

*Note.* All three functional forms were fit against the same six empirical targets described in the Method (main text): Linear = the primary form (main-text Tables 5–6); Censored = inflation floored at zero on all inflated scales; Freed skill = separate skill slopes for the Conscientiousness/Emotional Stability scales versus the self-esteem scale. Weighted distance = minimized weighted least squares criterion; Distance above A component = the same value minus the fixed Agreeableness-target penalty (approximately 3.5) that targeted inflation takes by construction, which is constant across forms within a context. Loss % = percentage reduction in mean true performance of hires; H gap = mean honesty-humility of applicants hired only under faking minus that of the applicants they displaced (pool *SD* units) at SR = .10, under the HEXACO honesty-humility correlations (Howard & Van Zandt, 2020; all other columns use this run) and under the overt integrity-test correlations (Sackett & Wanek, 1996, as cited in Lee et al., 2005; an otherwise identical run); SR = selection ratio. The censored and freed-skill forms fit better than the linear form in the US and pooled conditions; the non-US condition favors the linear form over the censored form and is indifferent between the linear and freed-skill forms. Produced by `16_study2_sixtarget_refit.py`.

**Table S11**

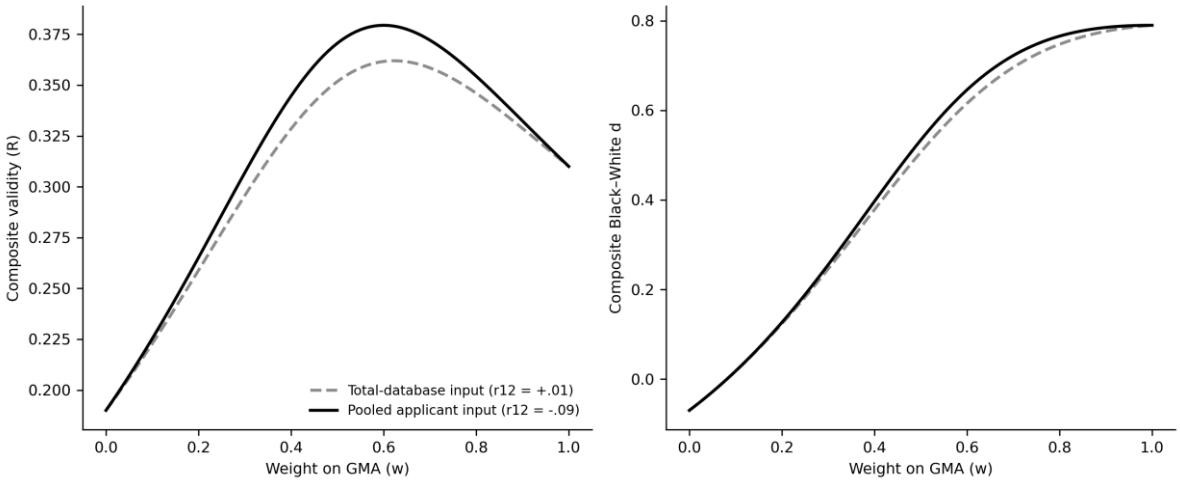

*Selection Outcomes for Every Trait–Faking Anchor Set Under the Six-Target Linear Fit*

| Context | Anchor set | Weighted distance | Fit supported | % changed, SR = .10 | % changed, SR = .30 | Loss %, SR = .10 | Loss %, SR = .30 |
|---|---|---|---|---|---|---|---|
| US | Field, conservative | 6.20 | Yes | 34.9 | 21.1 | 10.4 | 8.9 |
| US | Field | 8.17 | No | 33.1 | 19.5 | 11.3 | 9.4 |
| US | Laboratory | 3.79 | Yes | 30.9 | 24.4 | 6.8 | 7.1 |
| Pooled | Field, conservative | 4.95 | Yes | 28.8 | 21.5 | 7.9 | 9.2 |
| Pooled | Field | 6.56 | Yes | 29.2 | 20.7 | 8.4 | 9.6 |
| Pooled | Laboratory | 3.80 | Yes | 28.5 | 27.0 | 9.3 | 11.6 |
| Non-US | Field, conservative | 4.90 | Yes | 20.0 | 25.4 | 9.8 | 17.9 |
| Non-US | Field | 6.69 | Yes | 25.8 | 26.0 | 11.5 | 19.1 |
| Non-US | Laboratory | 6.57 | Yes | 37.7 | 41.3 | 39.1 | 48.2 |

*Note.* Uniform reporting rule: outcomes are reported for every anchor set in every condition; Fit supported = whether the set's weighted distance is within twice the condition minimum (the same heuristic threshold used in the one-parameter sensitivity analysis), so no row is withheld on plausibility grounds. Anchor sets are defined in the Method and main-text Table 5. % changed = percentage of top-down hires that differ from the honest counterfactual; Loss % = percentage reduction in mean true performance of hires; SR = selection ratio. The laboratory set's implied non-US losses (39%–48% of hire performance) lie far outside the range the faking-outcomes literature supports, which is the basis for the main text's conclusion that laboratory trait–faking estimates overstate operational damage; the rule reports the rows and lets the implausibility argument stand on its own. Produced by `16_study2_sixtarget_refit.py`.

**Figure S1**

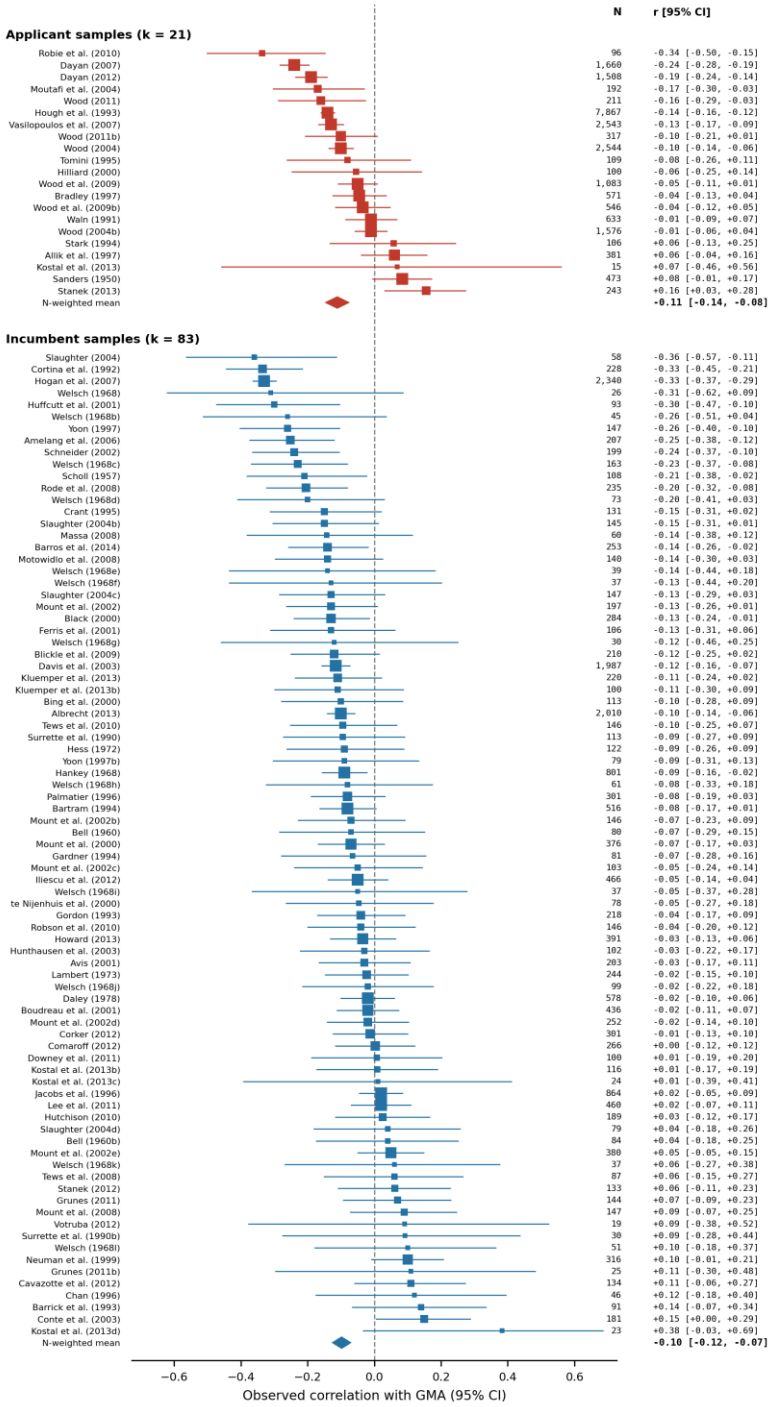

*Composite Validity and Subgroup Differences Under Total-Database Versus Pooled Applicant Intercorrelation Inputs*

*Note.* Composite validity (left) and composite Black–White *d* (right) for a GMA + Conscientiousness composite as a function of the weight on GMA, under the reliability-corrected total-database ($\rho_{12} = +.01$) versus pooled applicant ($\rho_{12} = -.09$) intercorrelation inputs. Inputs from Sackett et al. (2022), Roth et al. (2011), and Dahlke and Sackett (2017). GMA = general mental ability.

**Figure S2**

*Forest Plot of Neuroticism–GMA Correlations by Sample and Assessment Context*

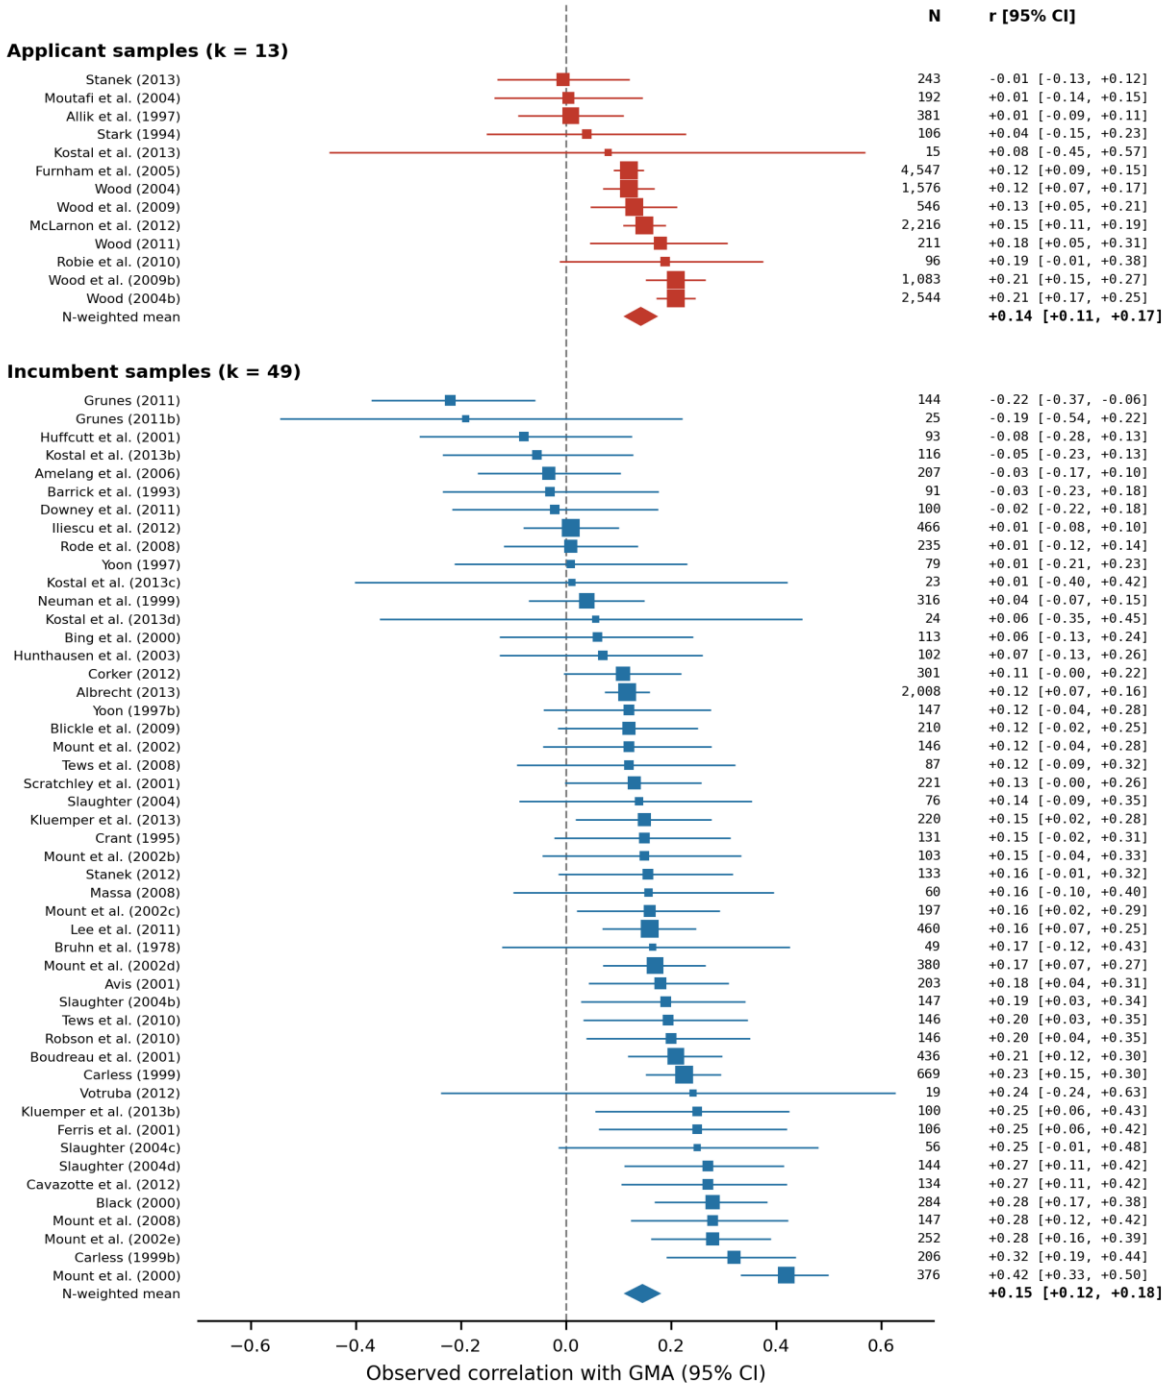

*Note.* Each row is one independent sample. Squares mark observed correlations, with area proportional to sample size; horizontal lines are 95% confidence intervals from the Fisher *r*-to-*z*

transformation. Diamonds mark the sample-size-weighted mean correlations with 95% confidence intervals. Samples are ordered from most negative to most positive within assessment context. Display conventions follow main-text Figure 2. GMA = general mental ability.

**Figure S3**

*Forest Plot of Openness–GMA Correlations by Sample and Assessment Context*

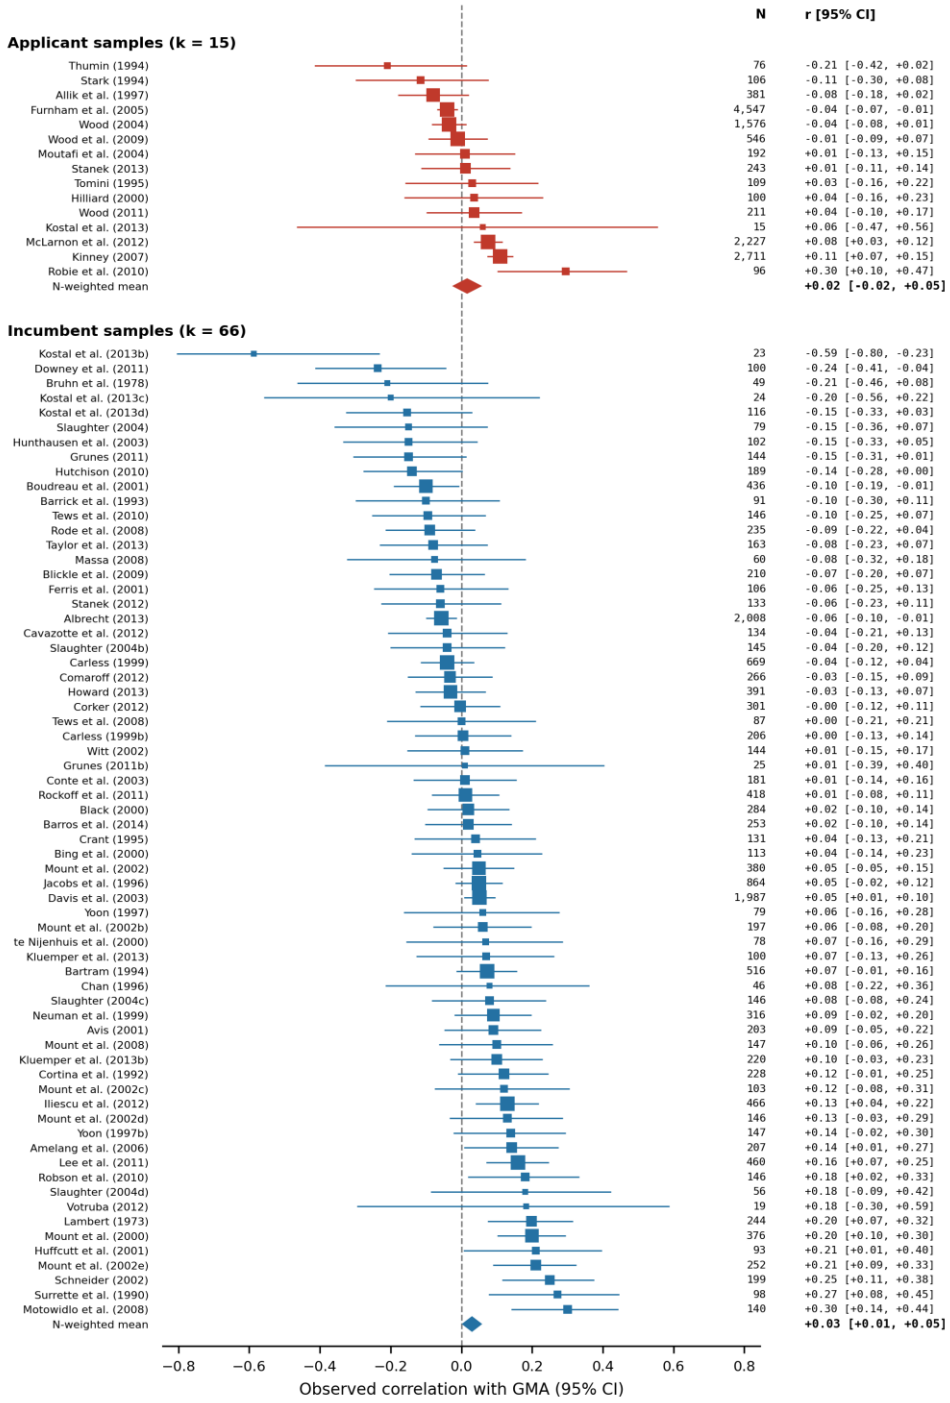

*Note.* Each row is one independent sample. Squares mark observed correlations, with area proportional to sample size; horizontal lines are 95% confidence intervals from the Fisher *r*-to-*z*

transformation. Diamonds mark the sample-size-weighted mean correlations with 95% confidence intervals. Samples are ordered from most negative to most positive within assessment context. Display conventions follow main-text Figure 2. GMA = general mental ability.

**Figure S4**

*Forest Plot of Extraversion–GMA Correlations by Sample and Assessment Context*

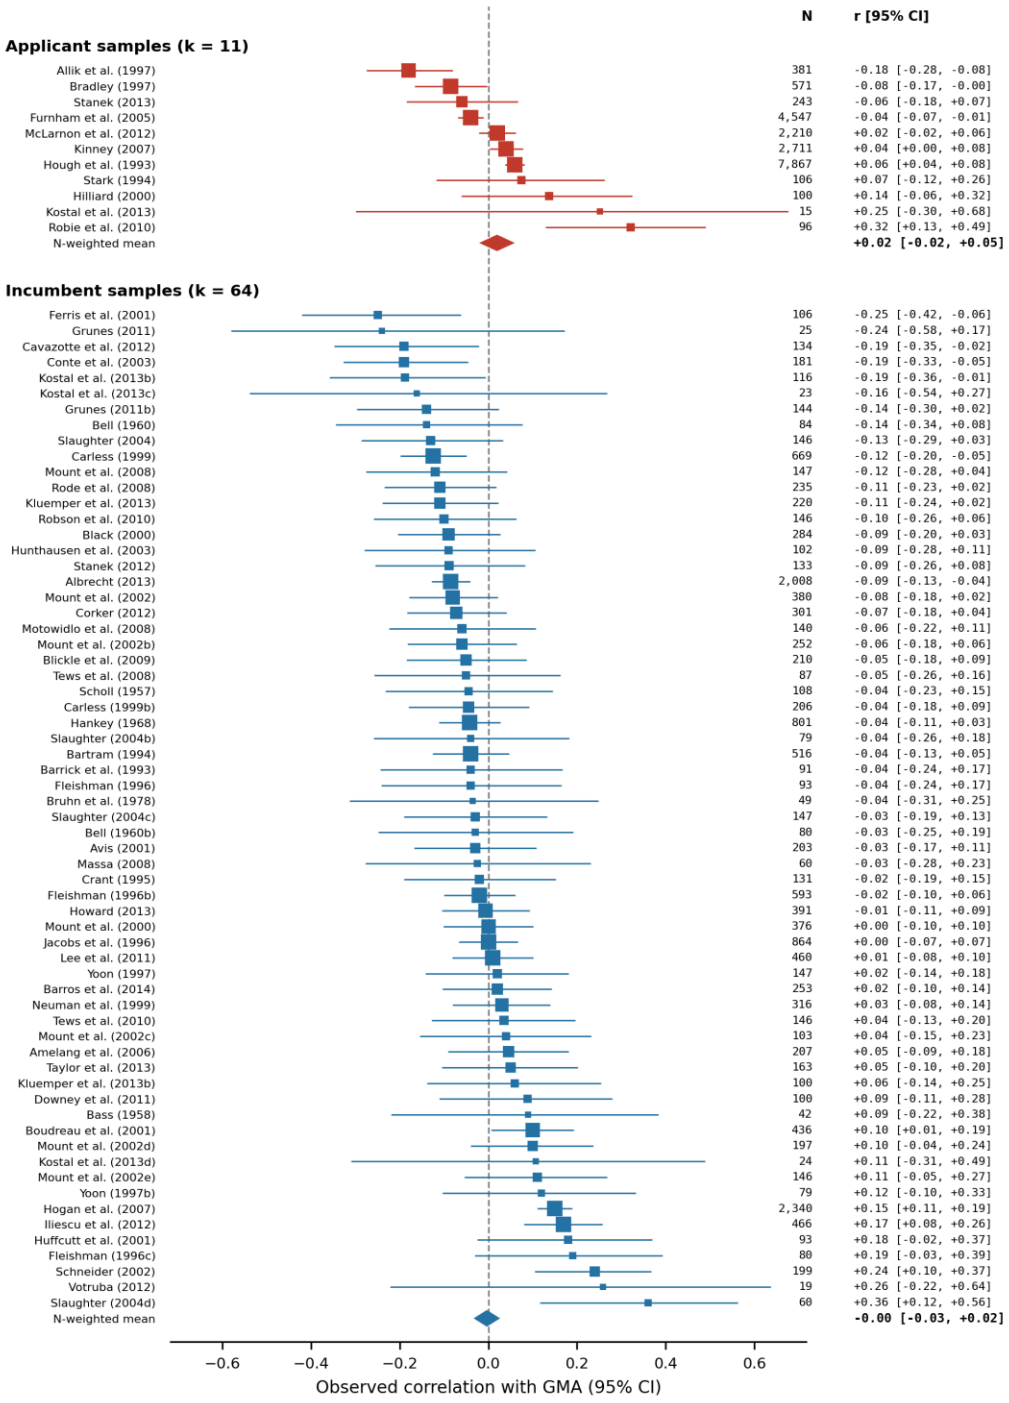

*Note.* Each row is one independent sample. Squares mark observed correlations, with area proportional to sample size; horizontal lines are 95% confidence intervals from the Fisher *r*-to-*z*

transformation. Diamonds mark the sample-size-weighted mean correlations with 95% confidence intervals. Samples are ordered from most negative to most positive within assessment context. Display conventions follow main-text Figure 2. GMA = general mental ability.

**Figure S5**

*Forest Plot of Agreeableness–GMA Correlations by Sample and Assessment Context*

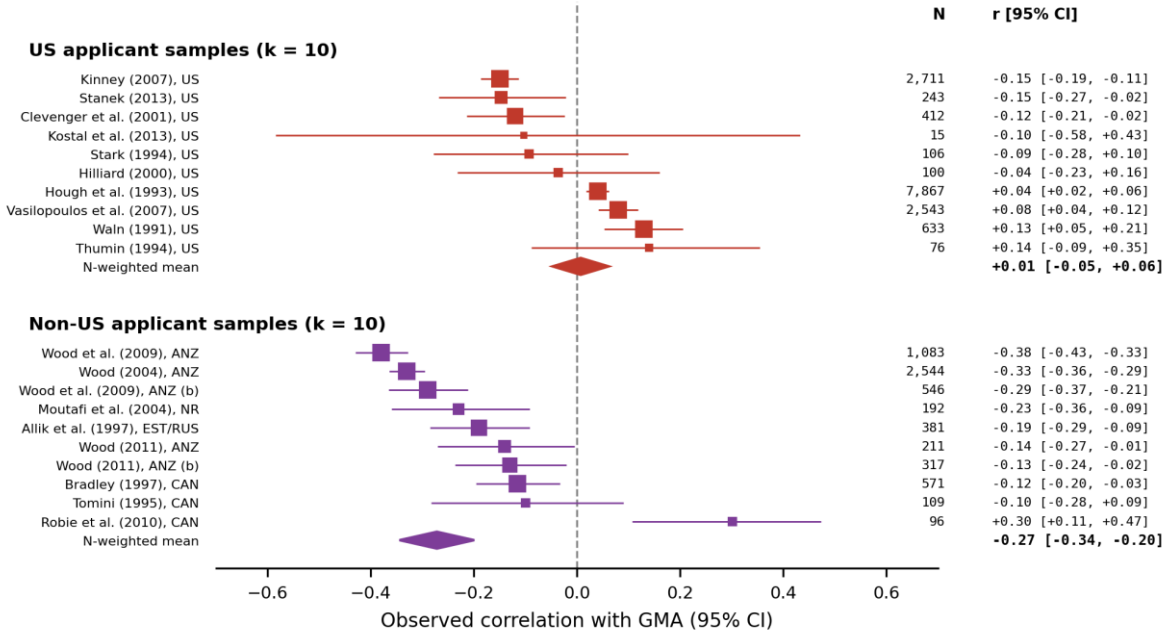

*Note.* Each row is one independent sample. Squares mark observed correlations, with area proportional to sample size; horizontal lines are 95% confidence intervals from the Fisher *r*-to-*z*

transformation. Diamonds mark the sample-size-weighted mean correlations with 95% confidence intervals. Samples are ordered from most negative to most positive within assessment context. Display conventions follow main-text Figure 2. GMA = general mental ability.

**Figure S6**

*Forest Plot of Conscientiousness–GMA Correlations for Applicant Samples by Region*

*Note.* Display conventions follow main-text Figure 2; country codes follow the database. The regional difference reported in Table 3, Panel A is one of subgroup means, not an absence of negative correlations among US samples; six of ten US applicant samples are negative, and the US mean (+.01) reflects the offsetting weight of the largest sample (Hough et al., 1993, $N$ = 7,868, $r$ = +.04). Five of the ten non-US samples come from a single research program (Wood, 2004, 2011; Wood & Englert, 2009; Australia/New Zealand) contributing 78% of the non-US applicant $N$; the remaining non-US samples are nonetheless uniformly negative except Robie et al. (2010). The sample without a reported country (Moutafi et al., 2004, a UK-based research group) is grouped with the non-US samples, matching the regional analysis. GMA = general mental ability; NR = not reported; ANZ = Australia/New Zealand; CAN = Canada; EST/RUS = Estonia/Russia. Sample-level correlations are from Stanek and Ones (2023c) and are not a redistribution of that database.
